

## Data Base Design

Our table's will look like this :

We Have a one-to-many connection between User's table and Post's table, because a user can have many posts, but a post has only one user who wrote it.

We have a many-to-many connection between User's table to follow table, because a user can have many followers and can be a follower to many users.

Id's are the primary key in those tables, As you demanded username is unique.

We added longitude and latitude in order to use this information to show the location in the map.

We have a relationship that called subscribes in Post table in order to show the subscribers of a post and when there will be a change in the post all subscribers will be notify.

Also We added City and Country fields in order to get more information about the travel location.
